#### **INTRODUCTION**

#### > Problem:

- Back-translated monolingual data improves NMT performance [1].
- > But it requires building a reverse NMT system which is expensive.

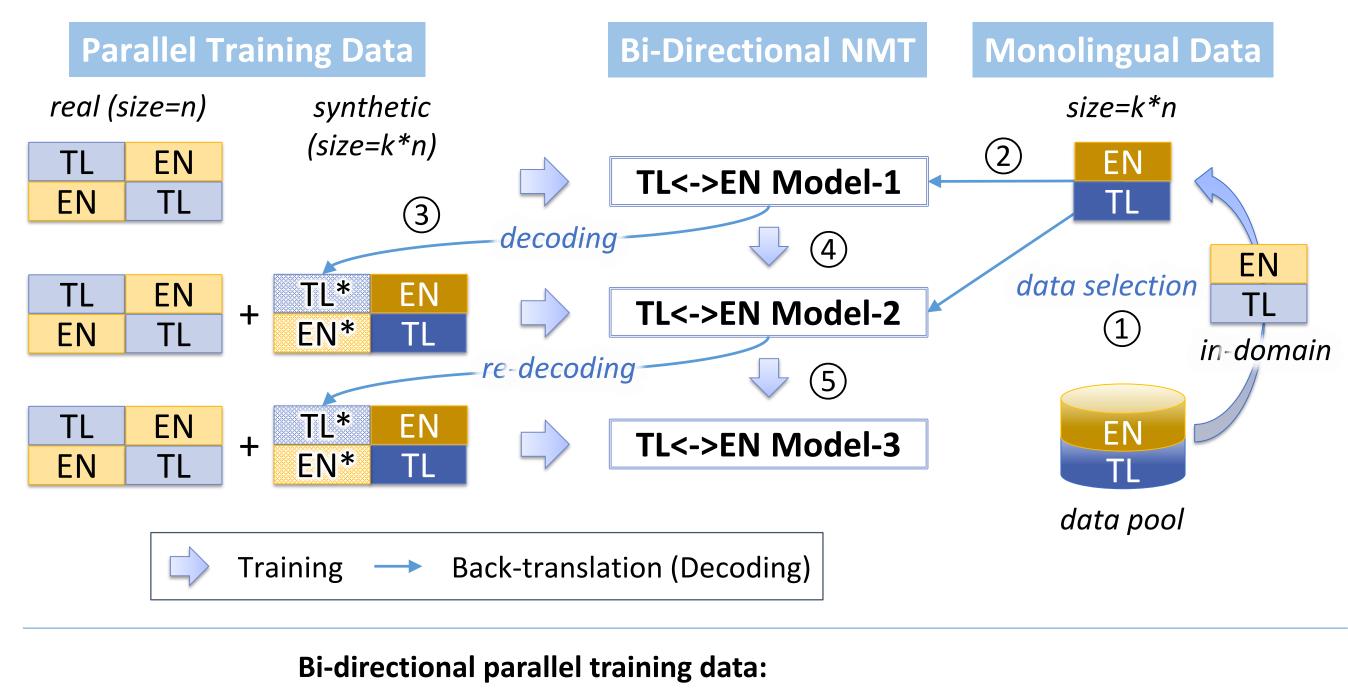

#### > Our solution:

- Combine back-translation with bi-directional NMT.
- > Inspired by multilingual NMT which reduces deployment complexity by packing multiple language pairs into a single model [2].

# 1) Select the monolingual data using cross-entropy difference [3].

- (2) Back-translate both source and target monolingual data by a single initial bi-directional NMT model (Model-1).
- (3) Always place the real (monolingual) data on the target side.
- (4) Fine-tune Model-1 on the augmented training data to get a stronger NMT model (Model-2).
- (5) Re-decode the monolingual data and fine-tune Model-2 to get an even stronger NMT model (Model-3).

# **APPROACH**

EN TL EN

- 1. Adding a language token (e.g. <2en>) to the source.
- 2. Swapping the source and target sentences and appending the swapped version to the original.

#### IN-DOMAIN EVALUATION (BLEU)

- Synthetic data (i.e. MT output) is annotated by asterisks.
- Largest improvements within each zone are highlighted.

#### Uni-directional models (U-x).

- Models trained on real target language data outperform using synthetic target language data (**U-2** vs. **U-3,4**).
- ➤ Bi-directional models (B-x).
  - > Combining all synthetic parallel data and always placing the MT output on the source side achieve best overall performance (B-5).
  - > Bi-directional models outperform the best uni-directional models for low-resource (EN-TL/SW) language pairs (**B-5** vs. **U-1**).
  - > Bi-directional models struggle to match performance in the high-resource (EN-DE) scenario (**B-5** vs. **U-2**).
  - ➤ Bi-directional models reduce the training time by 15-30% (B-5 vs. U-2).
- Fine-tuning and re-decoding.
  - > Instead of training from scratch (B-5), we can continue training baseline models (B-1) on augmented data and achieve comparable translation quality (B-5\*).
  - Fine-tuning significantly reduces cost by up to 20-40% computing time.
  - > Re-decoding the same monolingual data using improved models (B-5\*) leads to even stronger models (B-6\*).

**EXPERIMENTAL SETUP** 

> Training data:

| Language Pair   |       | <b>#Sentences</b> | Dataset   |  |
|-----------------|-------|-------------------|-----------|--|
| English-Tagalog | EN-TL | 50,705            | News/Blog |  |
| English-Swahili | EN-SW | 23,900            | News/Blog |  |
| English-German  | EN-DE | 4,356,324         | WMT News  |  |

- > In-domain test data:
  - ➤ News/Blog for EN-TL and EN-SW
  - ➤ News for EN-DE
- Out-of-domain test data:
  - ➤ Bible for EN-TL and EN-SW

# SIZE OF SYNTHETIC DATA $\longrightarrow$ EN $\rightarrow$ TL $\longrightarrow$ SW $\rightarrow$ EN (43)(42)36 (41) ⇒ 35 (40) 34 (39) 33 Size of synthetic data

> Using synthetic parallel data is always helpful, but when the size is larger than 5n, adding more contributes less (i.e. reaching the plateau) for our systems.

### **OUT-OF-DOMAIN EVALUATION (BLEU)**

|     |   | L2=TL               |                     | L2=SW               |                     |
|-----|---|---------------------|---------------------|---------------------|---------------------|
| ID  | Training Data (L1=EN)   | $TL \rightarrow EN$ | $EN \rightarrow TL$ | $SW \rightarrow EN$ | $EN \rightarrow SW$ |
| A-1 | $L1 \leftrightarrow L2$   | 11.03               | 10.17               | 6.56                | 3.80                |
| A-2 | $L1 \leftrightarrow L2 + L1 \star \rightarrow L2 + L2 \star \rightarrow L1$                           | 16.49               | 22.33               | 8.70                | 7.47                |
| A-3 | $L1 \leftrightarrow L2 + \underline{L1} \times \rightarrow L2 + \underline{L2} \times \rightarrow L1$ | 18.91               | 23.41               | 11.01               | 8.06                |

# > A long-distance domain adaptation task: News/Blog to Bible.

- > Domain mismatch is demonstrated by the extremely low BLEU scores of baseline News/Blog systems (A-1).
- > Selecting monolingual data which is closer to Biblical language.
- > After fine-tuning baseline models on augmented parallel data (A-2) and re-decoding (A-3), we see BLEU scores increase by 70-130%.

# CONCLUSION

- ➤ We introduce a bi-directional NMT protocol to effectively leverage monolingual data.
- > Training and deployment costs are reduced significantly compared to standard uni-directional systems.
- > It improves BLEU for low-resource languages, even over uni-directional systems with back-translation.
- > It is effective in domain adaptation.
